VIBRATION MITIGATION DEVICE**RELATED APPLICATIONS**

The present application claims priority to U.S. Provisional Patent Application No. 61/878,016.

BACKGROUND OF THE DISCLOSURE**1. Technical Field of the Disclosure**

The present invention is related in general to vibration mitigation systems, and in particular to a vibration mitigation device that incorporates a reciprocating assembly connected with a biasing member to mitigate vibration.

2. Description of the Related Art

Traffic signals are used extensively all over the world to control conflicting flows of traffic. The traffic signals are attached to tall traffic signal poles and horizontally extending mast arms or cables to ensure clear visibility of traffic signals for the drivers or pedestrians. Various types of signal support structures are currently employed, of which cantilevered support structures are widely used as traffic signal support structures since they consist of less material with only one vertical pole. However, cantilevered structures are flexible, lightly-damped structures that are highly susceptible to wind-induced vibration. The sustained large amplitude deflections due to excessive wind-induced vibrations can result in fatigue failure of the mast arm and vertical pole connection. This fatigue failure will ultimately lead to failure of these structures and represents a significant cost to signal owners.

Reducing the effective stress range in the structure by reducing the amplitude of the vibration can significantly increase the life of that structure. This can be done by increasing the damping of the structure with an effective damping device that would decrease the amplitude and number of cycles, thus extending the service life of the structure. A number of different methods have been suggested to increase the damping of the structure and reduce the excessive wind induced vibration of traffic poles. One such method employs a Signal Head Vibration Absorber (SHVA), which is a promising type of vibration absorber for traffic signal support structures. This device has been experimentally shown to increase the critical damping ratio of the traffic signal structures from less than 1% to over 10%, virtually eliminating any vibration, and protecting the structure from fatigue damage.

In a known prior art related to the vibration dampening systems, the damping assembly employs multiple doughnut shaped metal discs or weights vertically and loosely arranged in a unique fashion about a rod, disposed in a housing within the pole to reduce vibrations. However, the damper requires larger diameter poles which in turn would result in an over-sized support structure. Additionally, this class of damper, based on friction and/or impact damping, is amplitude dependent and may not be effective over certain ranges of vibration amplitudes.

Recent advancements in the art provide a vibration absorber, the SHVA noted above, for traffic signal supports. The SHVA utilizes the mass of the signal head in a configuration as a damped vibration absorber. The system also includes a spring and damper in mechanical communication with the signal head. However, the downside to this system is that the absorber requires utilization of the mass of the traffic signal which itself plays a critical function and the SHVA unit contains components exposed to the elements which requires regular maintenance.

2

Based on the foregoing there is a need for a vibration mitigation device which utilizes viscous or velocity dependent damping for energy dissipation, eliminates the utilization of the mass of the traffic signal and is self-contained with all critical components protected from the elements. Such a needed device would comprise a reciprocating assembly connected to a biasing member. The device would utilize a tension spring or a compression spring in an eddy current dampening process and/or a pneumatic process to dissipate energy and reduce vibrations. The present invention overcomes prior art shortcomings by accomplishing these critical objectives.

SUMMARY OF THE DISCLOSURE

To minimize the limitations found in the prior art, and to minimize other limitations that will be apparent upon the reading of the specification, the preferred embodiment of the present invention provides a vibration mitigation device which uses viscous or velocity dependent damping to dissipate energy, eliminates the utilization of the mass of the traffic signal and is self-contained with all critical components protected from the elements.

The present invention discloses a vibration mitigation device configured to be fixedly coupled to a generally horizontally extending support member. The vibration mitigation device includes a generally vertically extending housing extending from the generally horizontally extending support member and a reciprocating assembly coupled with and fully enclosed inside of the generally vertically extending housing. According to a first preferred embodiment, the reciprocating assembly includes a pair of opposing conducting rods disposed along a longitudinal path with respect to the generally vertically extending housing, a mass fixedly connected with a plurality of magnets arranged to provide a magnetic field across the pair of opposing conducting rods and configured to translate along the vertical path with respect to the generally vertically extending housing, a plurality of securing guides coupled with the mass and configured to allow the mass to reciprocate relative to the conducting rods and the vertically extending housing, and a biasing member configured to couple the reciprocating assembly with the generally vertically extending housing and configured to support the plurality of magnets and the mass in a neutral position with respect to the generally vertically extending housing when the vibration mitigation device is at rest. According to an alternative embodiment, the entirety or a portion of the housing itself may be used as the conducting material and the conducting rods may be eliminated.

In accordance with one embodiment of the present invention, the vibration mitigation device utilizes a tension spring as the biasing member in an eddy current dampening process. In this embodiment, the vibration mitigation device functions as an eddy current dampening device by generating eddy current when the conducting material is moved within the magnetic field of the device. In this embodiment, the conducting material is preferably disposed along the longitudinal path travelled by the mass and the plurality of magnets. Preferably, the pair of opposing conducting rods is configured with the plurality of magnets in such a way that the plurality of magnets move up and down relative to the pair of opposing conducting rods. In this configuration, the plurality of magnets dissipates the energy in the vibration mitigation device, resulting in motion dampening of the vibrating system.

3

In accordance with another exemplary embodiment of the present invention, the vibration mitigation device utilizes a tension spring as the biasing member in a pneumatic process. In this configuration, the vibration mitigation device includes a sealed outer case, an upper air chamber, the tension spring, a mass and a lower air chamber. The mass includes a pair of bushings that provides a contact surface for guiding the mass by the sealed outer case. The sealed outer case is pneumatically sealed and the mass is suspended by the tension spring and reciprocates vertically along the upper air chamber and the lower air chamber. During excessive vibrations in the support structure, the mass moves up and down in the sealed outer case, resulting in the exchange of air from one side of the mass to the other. This creates a suction or airflow resistance in the upper air chamber or lower air chamber, which slows the mass and dampens the vibration. In one embodiment, the mass includes side and/or interior relief conduits that allow air to communicate between the upper air chamber and the lower air chamber.

In accordance with yet another exemplary embodiment of the present invention, the vibration mitigation device utilizes a tension spring as the biasing member while operating in both the pneumatic process and the eddy current dampening process. This hybrid embodiment may work better over a wide spectrum of vibration amplitudes. For low amplitude, the eddy current dampening process may provide improved vibration mitigation results and for higher amplitudes, the pneumatic process may provide improved vibration mitigation results. Other exemplary embodiments provide a vibration damping element that utilizes a compression spring as a biasing member for mitigating vibrations. Further exemplary embodiments provide a vibration damping element that utilizes a compression spring and a tension spring as biasing members for mitigating vibrations.

These and other advantages and features of the present invention are described with specificity so as to make the present invention understandable to one of ordinary skill in the art.

BRIEF DESCRIPTION OF THE DRAWINGS

Elements in the figures have not necessarily been drawn to scale in order to enhance their clarity and improve understanding of these various elements and embodiments of the invention. Furthermore, elements that are known to be common and well understood to those in the industry are not depicted in order to provide a clear view of the various embodiments of the invention, thus the drawings are generalized in form in the interest of clarity and conciseness.

FIG. 1 is a perspective view of a preferred embodiment of a vibration mitigation device of the present invention;

FIG. 2 is an enlarged view of a reciprocating assembly incorporated within the vibration mitigation device of the present invention;

FIG. 3 is a partially cut-away schematic diagram of an exemplary vibration mitigation device of one embodiment of the present invention; and

FIG. 4 is a schematic diagram of the vibration mitigation device shown in FIG. 3, illustrating flow of air between an upper air chamber and a lower air chamber.

FIG. 5 is a perspective view of a preferred alternative embodiment of a vibration mitigation device of the present invention;

FIG. 6 is an enlarged view of a reciprocating assembly incorporated within a preferred alternative embodiment of a vibration mitigation device of the present invention; and

FIG. 7 is a schematic diagram of the vibration mitigation device shown in FIG. 6, illustrating flow of air between an upper air chamber and a lower air chamber.

DETAILED DESCRIPTION OF THE DRAWINGS

In the following discussion that addresses a number of embodiments and applications of the present invention, reference is made to the accompanying drawings that form a part hereof, and in which is shown by way of illustration specific embodiments in which the invention may be practiced. It is to be understood that other embodiments may be utilized and changes may be made without departing from the scope of the present invention.

Various inventive features are described below that can each be used independently of one another or in combination with other features. However, any single inventive feature may not address any of the problems discussed above or only address one of the problems discussed above. Further, one or more of the problems discussed above may not be fully addressed by any of the features described below.

FIG. 1 is a perspective view of a preferred embodiment of a vibration mitigation device **100** of the present invention. The vibration mitigation device **100** is configured to be fixedly coupled to a generally horizontally extending support member (not shown). The device **100** includes a generally vertically extending housing **112** with a second end cap **102**, a first end cap **108**, a pair of opposing conducting rods **126** disposed along a vertical path with respect to the generally vertically extending housing **112** and a reciprocating assembly **114** reciprocatingly coupled with the generally vertically extending housing **112**.

The reciprocating assembly **114** as shown preferably includes a mass **118** and a plurality of magnets **116** connected to the mass **118**. The magnets **116** are preferable configured to translate along a vertical path with respect to the generally vertically extending housing **112** and to thereby provide a magnetic field across the conducting rods **126**. As shown, the reciprocating assembly preferably further includes a plurality of guides **124** coupled with the mass **118** by at least one fastening element **120** and configured to allow the mass **118** to translate reciprocatingly by the pair of opposing conducting rods **126**. As further shown, the vertically extending housing **112** and a biasing member **122** are coupled to the reciprocating assembly **114**. The vertically extending housing **112** includes a first end cap **108** which connects to the biasing member **122** via a connecting element **128**. Preferably, the biasing member **122** is configured to support the plurality of magnets **116** and the mass **118** in a neutral position with respect to the generally vertically extending housing **112** when the vibration mitigation device **100** is at rest. The biasing member **122** includes at least one tension spring or a compression spring. The end caps **102** and **108** are preferably of unitary construction.

With reference now to FIG. 2, an enlarged view of the reciprocating assembly **114** incorporated within the vibration mitigation device **100** of the present invention is illustrated. In one embodiment, the vibration mitigation device **100** utilizes a tension spring as the biasing member **122** in an eddy current dampening process. In this embodiment, the vibration mitigation device **100** functions as an eddy current dampening device by generating eddy current when the pair of opposing conducting rods **126** is moved within the magnetic field of the device **100**. At rest, the mass **118** is suspended on the biasing member **122** within the generally vertically extending housing **112**. When vibrational force is

5

applied, the mass **118** reciprocates up and down within the generally vertically extending housing **112**.

According to a further aspect of the first preferred embodiment, the pair of opposing conducting rods **126** are preferably formed of conducting material and placed along the vertical path travelled by the mass **118** and the plurality of magnets **116**. Preferably, the pair of opposing conducting rods **126** are secured within the vertically extending housing **112** in such a way that the plurality of magnets **116** moves up and down relative to and provides a magnetic field across the pair of opposing conducting rods **126**. In this process, the plurality of magnets **116** create eddy currents in the conducting material which dissipates the energy of the vibration mitigation device **100**, resulting in motion dampening of the support member. The conducting material of conducting rods **126** may preferably be formed from any non-ferrous metal(s). For example, in one embodiment, the conducting material may include aluminum, copper, gold, silver or a combination thereof. The plurality of magnets **116** may include a permanent magnetic material, a ferromagnetic material, a ferromagnetic material or an electromagnet. The plurality of guides **124** are preferably coupled with the mass **118** by at least one fastening element **120**.

In one embodiment, the eddy current dampening device generates electricity, which is sufficient to run an LED light.

In an alternative exemplary embodiment of the present invention, as shown in FIGS. **3** and **4**, a vibration mitigation device **200** utilizes a tension spring **208** as the biasing member in a pneumatic process. The vibration mitigation device **200** includes a sealed outer case **202**, an upper air chamber **204**, a tension spring **208**, a mass **210** and a lower air chamber **206**. The mass **210** includes a pair of bushings **212** that provide a contact surface for guiding the mass **210** within the sealed outer case **202**. In one embodiment, the mass **210** includes a plurality of stacked weights that are stacked together by at least one fastening element **214**. The at least one fastening element **214** may include nuts and bolts.

The sealed outer case **202** is preferably pneumatically sealed and the mass **210** is suspended by the tension spring **208** and allowed to reciprocate vertically. During excessive vibrations in the support structures, the mass **210** is preferably configured to move up and down in the sealed outer case **202** resulting in exchange of air from one side of the mass **210** to the other. This creates a suction or airflow resistance in the upper air chamber **204** or lower air chamber **206** to slow the mass **210** and dampen the vibration. In one embodiment, the mass **210** includes side and/or interior relief conduits that allow air to communicate between the upper air chamber **204** and the lower air chamber **206**.

FIG. **4** is a schematic diagram of the vibration mitigation device **200** shown in FIG. **3**, illustrating a flow of air between the upper air chamber **204** and the lower air chamber **206**. As shown, the motion of the mass **210** suspended by the tension spring **208** is excited through the motion of the mass arm that the device **200** is attached to and is indicated by the arrow **216**. As further shown in FIG. **4**, as the mass **210** travels up and down inside the sealed outer case **202**, the volume of air between the upper air chamber **204** and the lower air chamber **206** changes. Specifically, as the mass **210** strokes downward, volume of the lower air chamber **206** decreases and the upper air chamber **204** increases. As volume of the lower air chamber **206** decreases, pressure increases, causing a resistance resulting in an upward damping force on the mass **210**. Conversely, as the mass **210** strokes upward, the volume in the lower air chamber **206** increases and the volume of the upper air

6

chamber **204** decreases. When the volume of the lower air chamber **206** increases, the pressure decreases, resulting in a damping force opposing the motion of the mass **210**. The exchange of volume between the upper air chamber **204** and the lower air chamber **206** is indicated by the arrow **218**. The amount of air exchanged may be adjusted by various elements including but not limited to: orifice plates drilled through the mass, valves and internal clearances.

FIG. **5** is a perspective view of a preferred alternative embodiment of a vibration mitigation device **500** of the present invention. As shown, the vibration mitigation device **500** includes a generally vertically extending housing **502**, a reciprocating assembly **510** arranged for reciprocating movement within the housing **502** and spring **508**. According to a preferred embodiment, the spring **508** may be a tension spring, a compression spring or the like.

With reference now to FIGS. **6** and **7**, a detailed explanation of an alternative preferred embodiment as shown in FIG. **5** shall now be discussed. As shown in FIG. **6**, a cut-way view is provided illustrating the interiors of the vertical housing assembly **602** (referred to as **502** in FIG. **5**) and the reciprocating assembly **610** (referred to as **510** in FIG. **5**). As shown, the vibration mitigation device **600** may preferably include a tension spring **608** as the biasing member in a pneumatic process, with the tension spring **608** attached to reciprocating mass assembly **610**. As further shown, the reciprocating assembly **610** may be constructed as a cast iron weight **614** sealed within the reciprocating assembly **610** and may further include an upper slide bearing **612** and a lower slide bearing **613** to guide the movement of the reciprocating assembly **610**. To assist and control air flow within the vertical housing assembly **602**, the reciprocating assembly **610** may further include upper pneumatic air passages **622** and lower pneumatic air passages **618**. Additionally, the reciprocating assembly **610** as shown may preferably further include a cushioning element **616** as well as a magnet element **620**. According to a further preferred embodiment, magnet element **620** may be a rare earth magnet and cushioning element **616** may be a rubber bumper or the like.

As further shown in FIG. **6**, the top slide bearing **612** further includes upper pneumatic passage wings **617a** and **617b** which extend downward from the top slide bearing **612** to form slanted top surfaces **623a** and **623b**. Similarly, the bottom slide bearing **613** includes lower pneumatic passage wings **619a** and **619b** which extend upward from the bottom of slide bearing **613** to form slanted top surfaces **625a** and **625b**.

FIG. **7** is a schematic diagram of the vibration mitigation device shown in FIG. **6**. As shown, FIG. **7** illustrates the flow of air between the upper pneumatic air passages **724** and the lower pneumatic air passages **726**. As discussed above with respect to other embodiments, the motion of the reciprocating assembly **710** suspended by the tension spring **708** is excited through the motion of the mass arm that the device **700** is attached to (not shown). As discussed above, in response to vibrational forces, the reciprocating assembly **710** travels up and down inside the sealed outer case **702** which results in a change in volume between the upper air chamber **704** and the lower air chamber **706**. Specifically, as the reciprocating assembly **710** strokes downward, the volume of the lower air chamber **706** decreases and the volume of the upper air chamber **704** increases. As the air volume of the lower air chamber **706** decreases, the pressure increases, causing a resistance resulting in an upward damping force on the reciprocating assembly **710**. Conversely, as the reciprocating assembly **710** strokes upward, the volume of the

7

lower air chamber **706** increases and the volume of upper air chamber **704** decreases. When the volume of the lower air chamber **706** increases, the pressure decreases, resulting in a damping force opposing the motion of the reciprocating assembly **710**.

As detailed in FIG. 7, according to an alternative preferred embodiment, the exchange of volume between the upper air chamber **704** and the lower air chamber **706** is preferably directed through the upper pneumatic air passages **724** and the lower pneumatic air passages **726** as indicated by the arrow **728**. The amount of air exchanged may be adjusted by various elements including but not limited to: orifice plates drilled through the mass, valves and internal clearances.

As further shown in FIG. 7, the reciprocating assembly **710** preferably further includes a magnet element **720**. As discussed above, magnet element **720** preferably creates eddy currents in surrounding conducting materials which dissipates the energy of the vibration mitigation device **700**, resulting in motion dampening. Preferably, magnet element **720** is comprised of a rare earth magnet. Alternatively, magnet element **720** may be formed of any permanent magnetic material, ferromagnetic material, ferromagnetic material or an electromagnet.

According to a further aspect of the present invention, the conductive materials of the present invention may be incorporated into the structure of the sealed outer case **702**. According to a preferred embodiment, the sealed outer case **702** may be lined with conductive material. Alternatively, the conductive material may be incorporated into the entirety of the wall structure of the sealed outer case **702** or only embedded within discrete section(s) of the sealed outer case **702**.

In another exemplary embodiment of the present invention, a tension spring is utilized as the biasing member when the vibration mitigation device operates in both the pneumatic process and the eddy current dampening process as described above. This hybrid embodiment may work better over a wide spectrum of vibration amplitudes. For low amplitudes, the eddy current dampening process may provide improved vibration mitigation results and for higher amplitudes, the pneumatic process may provide improved vibration mitigation results. Other exemplary embodiments provide a vibration damping element that utilizes a compression spring as a biasing member for mitigating vibrations. Further exemplary embodiments provide a vibration damping element that utilizes a compression spring and a tension spring as biasing members for mitigating vibrations.

According to a further preferred embodiment, the present invention may use a hydraulic or other liquid based pressure source in place of the pneumatic (air) pressure source discussed above. Accordingly, hydraulic fluid, oil, water or another liquid may be used within the vibration dampening element to allow for pressure adjustments between the upper and lower chambers of the vertically extending housing as discussed above.

In one embodiment, the present invention includes a vibration mitigation device that can be configured to reduce naturally induced vibrations and attached to a variety of support structures including at least one of a bridged structure, a cantilever or a multi-pole support system holding or supporting lighting, traffic signals, street signs, signage, cameras or other devices.

The foregoing description of the preferred embodiment of the present invention has been presented for the purpose of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise form disclosed.

8

Many modifications and variations are possible in light of the above teachings. It is intended that the scope of the present invention not be limited by this detailed description, but by the claims and the equivalents to the claims appended hereto.

We claim:

1. A vibration mitigation apparatus, wherein the vibration mitigation apparatus comprises:

a vertically extending housing, wherein the vertically extending housing comprises:

a first end cap;
a second end cap; and
a centrally enclosed area;

a reciprocating assembly, wherein the reciprocating assembly is enclosed within the vertically extending housing and configured to move vertically within the vertically extending housing; wherein the reciprocating assembly comprises a top surface and a bottom surface;

a top slide bearing, wherein the top slide bearing comprises a plurality of upper air passages; wherein the top slide bearing is comprised of a body extending around the outer circumference of the top surface of the reciprocating assembly; further wherein the plurality of upper air passages are formed within the top slide bearing and spaced around the outer circumference of the top surface of the reciprocating assembly;

a bottom slide bearing, wherein the bottom slide bearing comprises a plurality of lower air passages; wherein the bottom slide bearing is comprised of a body extending around the outer circumference of the bottom surface of the reciprocating assembly; further wherein the plurality of lower air passages are formed within the bottom slide bearing and spaced around the outer circumference of the bottom surface of the reciprocating assembly; and

a biasing member, wherein the biasing member is attached to the vertically extending housing and to the reciprocating assembly, wherein the biasing member is configured to support the mass in a neutral position with respect to the vertically extending housing when the vibration mitigation apparatus is at rest.

2. The apparatus of claim 1, wherein the reciprocating assembly comprises one or more weight elements which are configured to increase the weight of the reciprocating assembly.

3. The apparatus of claim 2, wherein the biasing element is comprised of a tension spring.

4. The apparatus of claim 3, wherein the biasing element is comprised of a compression spring.

5. A vibration mitigation apparatus, wherein the vibration mitigation apparatus comprises:

a vertically extending housing, wherein the vertically extending housing comprises:

a first end cap;
a second end cap; and
a centrally enclosed area;

a reciprocating assembly, wherein the reciprocating assembly is enclosed within the vertically extending housing and configured to move vertically within the vertically extending housing; wherein the reciprocating assembly comprises a top surface and a bottom surface;

a top slide bearing, wherein the top slide bearing comprises a plurality of upper air passages; wherein the top slide bearing is comprised of a body extending around the outer circumference of the top surface of the

9

reciprocating assembly; further wherein the plurality of upper air passages are formed within the top slide bearing and spaced around the outer circumference of the top surface of the reciprocating assembly;

further wherein the top slide bearing further comprises an upper pneumatic passage wing; wherein the upper pneumatic passage wing extends downward from the top slide bearing to form a first slanted, distal surface; and

a bottom slide bearing, wherein the bottom slide bearing comprises a plurality of lower air passages; wherein the bottom slide bearing is comprised of a body extending around the outer circumference of the bottom surface of the reciprocating assembly; further wherein the plurality of lower air passages are formed within the bottom slide bearing and spaced around the outer circumference of the bottom surface of the reciprocating assembly;

further wherein the bottom slide bearing comprises a lower pneumatic passage wing; wherein the lower pneumatic passage wing extends upward from bottom slide bearing to form a second slanted, distal surface; and

a biasing member, wherein the biasing member is attached to the vertically extending housing and to the reciprocating assembly, wherein the biasing member is

10

configured to support the mass in a neutral position with respect to the vertically extending housing when the vibration mitigation apparatus is at rest; and

a magnetic element, wherein the magnetic element is attached to the reciprocating assembly and further wherein the magnetic element is configured to produce eddy currents as the reciprocating assembly moves vertically within the vertically extended housing.

6. The apparatus of claim 5, wherein the apparatus further comprises a conducting element.

7. The apparatus of claim 6, wherein the vertically extending housing further comprises at least one portion of the housing which is comprised of a conducting material.

8. The apparatus of claim 6, wherein the conducted element comprises a conducting rod.

9. The apparatus of claim 8, wherein the magnet element is comprised of a rare earth magnet.

10. The apparatus of claim 9, wherein the reciprocating assembly comprises one or more weight elements which are configured to increase the weight of the reciprocating assembly.

11. The apparatus of claim 10, wherein the biasing element is comprised of a tension spring.

12. The apparatus of claim 10, wherein the biasing element is comprised of a compression spring.
